Profitability Forecast

Based on nearly 40 years of data collected by the International Finance Corporation (IFC), this report offers a comprehensive analysis of default rates for the IFC corporate loan portfolio. It provides information potentially useful to understand credit performance in emerging markets.

The report presents aggregate default rates as well as variations observed across different parameters such as industry, region, and country income group. Using a more limited data set, since 2017, the report shows default rates by IFC's internal credit risk rating.

Over the period from 1986 to 2023, the IFC's portfolio exhibited a default rate of 4.1%. The highest historical default rates were observed in 1986 and 2003, reaching 11.5% and 10.3%, respectively. The analysis reveals that the manufacturing, agribusiness, and services industry group exhibited the highest default rates, followed by infrastructure, and financial institutions.

Looking at the split of default rates across World Bank regions, Africa exhibited a default rate of 6.7%, driven primarily by investments in the earlier part of the observed period, while all other regions ranged between 3.2% and 4.5%. Looking at the data by country income group, low-income economies exhibit the highest default rates with 8.6%. Based on a more limited data set, from 2017, annual default rates generally correlate with risk rating.

The first sections provide technical details about the methodology and the composition of the underlying data. The following sections present default rates and insights across relevant dimensions.

Key Features

Discover what Loanlens offers

- AI-powered loan analysis
- Multi-language translation support
- Fairness check score feature
- Risk assessment for lenders
